Aim

To create an interactive retail sales dashboard using Tableau to analyze sales performance, profit, product categories, monthly sales trends, and order-value distribution through charts, filters, and visualizations.

Description

Tableau is a data visualization and business intelligence tool used to represent data graphically and generate meaningful insights. In this experiment, a retail sales dataset containing order details, dates, products, categories, regions, sales, quantities, and profits is imported into Tableau.

Different visualizations, such as bar charts, line charts, pie charts, histograms, and scatter plots, are created using worksheets. Calculated fields are used to analyze total sales, total profit, and profit margin. These worksheets are combined into an interactive dashboard, with filters for region and category, to support effective data exploration and business decision-making.

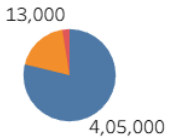

Observation

1. The bar chart compares sales across different product categories.
2. The line chart identifies monthly sales trends and fluctuations.
3. The pie chart displays each category's contribution to total sales.
4. The histogram shows the distribution of order sales values.
5. The scatter plot helps analyze the relationship between sales and profit.
6. Interactive filters allow users to explore sales data by region and category.
7. The dashboard presents key business insights in a clear and organized visual format.

Result

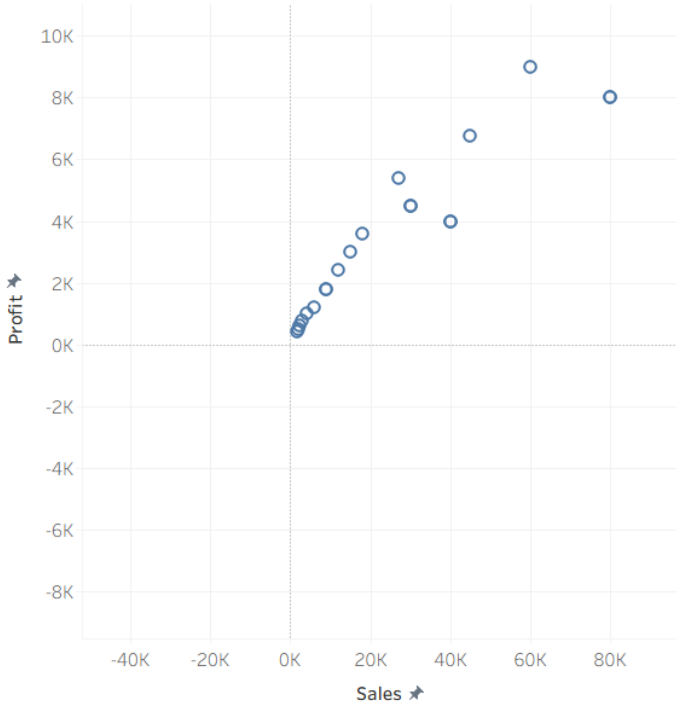

An interactive retail sales dashboard was successfully created using Tableau. The visualizations helped analyze category-wise sales, monthly trends, order-value distribution, and profitability, enabling effective data interpretation and decision-making.
